

Notes on Characteristic Functions

Dec. 32, 2999

For an underlying S_t following certain stochastic process, its characteristic function is defined as

$$\varphi(u) = E[e^{iuX_T} | X_t], \quad (1)$$

where $X_t = \log S_t$.

1 Fourier Inversion Formula

Consider the problem of finding the in-the-money (ITM) probability of the underlying asset at maturity, $P(\log S_T > \log K)$, which is given by

$$P(\log S_T > k) = \int_k^{+\infty} f(x) dx, \quad (2)$$

with $k = \log K$. Here, $f(x)$ is the probability density function of $X_T = \log S_T$, and can be recovered from the characteristic function (1) by the inverse Fourier transform,

$$f(x) = \frac{1}{2\pi} \int_{-\infty}^{+\infty} e^{-iux} \varphi(u) du. \quad (3)$$

Therefore,

$$\begin{aligned} P(\log S_T > k) &= \frac{1}{2\pi} \int_k^{+\infty} \left(\int_{-\infty}^{+\infty} e^{-iux} \varphi(u) du \right) dx = \frac{1}{2\pi} \int_{-\infty}^{+\infty} \varphi(u) \left(\int_k^{+\infty} e^{-iux} dx \right) du \\ &= \frac{1}{2\pi} \int_{-\infty}^{+\infty} \varphi(u) \frac{e^{-iuk}}{iu} du - \frac{1}{2\pi} \lim_{R \rightarrow +\infty} \int_{-\infty}^{+\infty} \varphi(u) \frac{e^{-iuR}}{iu} du. \end{aligned} \quad (4)$$

To evaluate the second term, we again use the definition of the characteristic function,

$$\begin{aligned} \frac{1}{2\pi} \lim_{R \rightarrow +\infty} \int_{-\infty}^{+\infty} \varphi(u) \frac{e^{-iuR}}{iu} du &= \frac{1}{2\pi} \lim_{R \rightarrow +\infty} \int_{-\infty}^{+\infty} \left(\int_{-\infty}^{+\infty} e^{iux} f(x) dx \right) \frac{e^{-iuR}}{iu} du \\ &= \frac{1}{2\pi} \lim_{R \rightarrow +\infty} \int_{-\infty}^{+\infty} f(x) \left(\int_{-\infty}^{+\infty} \frac{e^{iu(x-R)}}{iu} du \right) dx \\ &= \frac{1}{2\pi} \lim_{R \rightarrow +\infty} \int_{-\infty}^{+\infty} f(x) \cdot \pi \operatorname{sgn}(x - R) dx \\ &= \frac{1}{2} \lim_{R \rightarrow +\infty} (1 - 2F(R)) = -\frac{1}{2}. \end{aligned} \quad (5)$$

Here, we have used the fact that

$$\int_{-\infty}^{+\infty} \text{sgn}(x-y)f(x)dx = \int_y^{+\infty} f(x)dx - \int_{-\infty}^y f(x)dx = 1 - 2F(y), \quad (6)$$

where $F(x)$ is the cumulative distribution function of X_T .

Finally, the ITM probability is given by

$$P(\log S_T > k) = \frac{1}{2} + \frac{1}{2\pi} \int_{-\infty}^{+\infty} \varphi(u) \frac{e^{-iuk}}{iu} du. \quad (7)$$

2 Vanilla option pricing with characteristic functions

In the following, we are going to explore several formulations of vanilla option prices in terms of characteristic functions.

2.1 Heston [1]

Consider the call option price

$$C(K) = e^{-r(T-t)} \mathbb{E}^{\mathbb{Q}} [(S_T - K)^+], \quad (8)$$

under the risk neutral measure. We are seeking a representation similar to the Black-Scholes formula. To this end, we can write the call option prices as

$$C(K) = e^{-r(T-t)} \mathbb{E}^{\mathbb{Q}} [(S_T - K) \mathcal{I}_{S_T > K}], \quad (9)$$

where \mathcal{I} is the indicator function. Now, we have

$$C(K) = e^{-r(T-t)} \mathbb{E}^{\mathbb{Q}} [S_T \mathcal{I}_{S_T > K}] - K e^{-r(T-t)} \mathbb{E}^{\mathbb{Q}} [\mathcal{I}_{S_T > K}] = S_t P_1 - K e^{-r(T-t)} P_2, \quad (10)$$

where

$$P_1 = \mathbb{E}^{\mathbb{Q}} \left[\frac{S_T/S_t}{B_T/B_t} \mathcal{I}_{S_T > K} \right], \quad P_2 = \mathbb{E}^{\mathbb{Q}} [\mathcal{I}_{S_T > K}]. \quad (11)$$

It is obvious that P_2 is the risk neutral probability for the underlying asset maturing in-the-money. Also, P_1 can be represented as the ITM probability in another measure. Notice that

$$\frac{d\mathbb{Q}}{d\mathbb{Q}^S} = \frac{B_T/B_t}{S_T/S_t} = \frac{\mathbb{E}^{\mathbb{Q}}[e^{X_T}]}{e^{X_T}}, \quad (12)$$

where we have used the fact that

$$\mathbb{E}^{\mathbb{Q}}[S_T] = \mathbb{E}^{\mathbb{Q}}[e^{X_T}] = S_t \frac{B_T}{B_t}, \quad (13)$$

then

$$P_1 = \mathbb{E}^{\mathbb{Q}^S} \left[\frac{S_T/S_t}{B_T/B_t} \mathcal{I}_{S_T > K} \frac{d\mathbb{Q}}{d\mathbb{Q}^S} \right] = \mathbb{E}^{\mathbb{Q}^S} [\mathcal{I}_{S_T > K}]. \quad (14)$$

From Eq. (7), the two probabilities P_1 and P_2 can be written as

$$P_j = \frac{1}{2} + \frac{1}{2\pi} \int_{-\infty}^{+\infty} \varphi_j(u) \frac{e^{-iuk}}{iu} du, \quad j = 1, 2. \quad (15)$$

It seems that two characteristic functions corresponding to the two different measures are required in the valuation of the option price. However, these two characteristic functions are related due to the measure change. To see this, notice that

$$\varphi_1(u) = \int_{-\infty}^{+\infty} e^{iux} f^S(x) dx, \quad (16)$$

where $f^S(x)$ is the probability density function of X_T under the \mathbb{Q}^S -measure. It is related to $f(x)$, the probability density function of X_T under the \mathbb{Q} -measure, through the measure change,

$$f^S(x) = f(x) \frac{d\mathbb{Q}^S}{d\mathbb{Q}} = f(x) \frac{e^{X_T}}{\mathbb{E}\mathbb{Q}[e^{X_T}]}. \quad (17)$$

Now,

$$\varphi_1(u) = \frac{1}{\mathbb{E}\mathbb{Q}[e^{X_T}]} \int_{-\infty}^{+\infty} e^{ix(u-i)} f(x) dx = \frac{\varphi(u-i)}{\varphi(-i)}, \quad (18)$$

since

$$\mathbb{E}\mathbb{Q}[e^{X_T}] = \int_{-\infty}^{+\infty} e^x f(x) dx = \varphi(-i), \quad (19)$$

where $\varphi(u)$ is the characteristic function as defined in (1), and coincides with $\varphi_2(u)$. Therefore,

$$P_1 = \frac{1}{2} + \frac{1}{2\pi} \int_{-\infty}^{+\infty} \frac{e^{-iu \log K} \varphi(u-i)}{iu \varphi(-i)} du, \quad (20)$$

$$P_2 = \frac{1}{2} + \frac{1}{2\pi} \int_{-\infty}^{+\infty} \frac{e^{-iu \log K} \varphi(u)}{iu} du. \quad (21)$$

$$(22)$$

2.2 Carr and Madan [2]

The call option price can be represented as

$$C(k) = e^{-r(T-t)} \int_k^{+\infty} (e^x - e^k) f(x) dx, \quad (23)$$

where $k = \log K$, $x = \log S_T$, and $f(x)$ is the probability density function for the distribution of x at maturity. We want to find the Fourier transform of the above call option price, but it is not integrable. To remedy this, we introduce a damping factor and modify the call option price accordingly,

$$c(k) = e^{\alpha k} C(k), \quad (24)$$

and the corresponding Fourier transform is given by

$$\hat{c}(v) = \int_{-\infty}^{+\infty} e^{ivk} c(k) dk. \quad (25)$$

Rearrange the integration order, we have

$$\begin{aligned} \hat{c}(v) &= e^{-r(T-t)} \int_{-\infty}^{+\infty} e^{ivk} \left(\int_k^{+\infty} e^{\alpha k} (e^x - e^k) f(x) dx \right) dk \\ &= e^{-r(T-t)} \int_{-\infty}^{+\infty} f(x) \left(\int_{-\infty}^x (e^{(\alpha+iv)k} e^x - e^{(\alpha+iv+1)k}) dk \right) dx \\ &= e^{-r(T-t)} \int_{-\infty}^{+\infty} f(x) \left[\frac{e^{(\alpha+iv)k} e^x}{\alpha + iv} - \frac{e^{(\alpha+iv+1)k}}{\alpha + iv + 1} \right] \Big|_{-\infty}^x dx \\ &= e^{-r(T-t)} \int_{-\infty}^{+\infty} f(x) \left[\frac{e^{(\alpha+iv+1)x}}{\alpha + iv} - \frac{e^{(\alpha+iv+1)x}}{\alpha + iv + 1} \right] dx \\ &= e^{-r(T-t)} \int_{-\infty}^{+\infty} f(x) \frac{e^{(\alpha+iv+1)x}}{(\alpha + iv)(\alpha + iv + 1)} dx \\ &= \frac{e^{-r(T-t)} \varphi(v - (1 + \alpha)i)}{(\alpha + iv)(\alpha + iv + 1)}, \end{aligned} \quad (26)$$

where $\alpha > 0$ is necessary to ensure convergence at $k = -\infty$. Once the Fourier transform of the modified call option price is known, we can use the inverse Fourier transform to recover the call option price,

$$C(k) = \frac{e^{-\alpha k}}{2\pi} \int_{-\infty}^{+\infty} e^{-ivk} \hat{c}(v) dv. \quad (27)$$

2.3 Lewis [3]

Denote the payoff the contingent claim at maturity as $g(x)$, then the value of the derivative is given by

$$V = \int_{-\infty}^{+\infty} f(x) g(x) dx. \quad (28)$$
